## HYPERCALCEMIA IN MALIGNANCY ABSTRACT

Hyperparathyroidism and malignancies are responsible in more than 90% cases of hypercalcemia. The cancer of lung, breast, kidney as well as haematologic malignancies (including multiple myeloma) are the most often presented with hypercalcemia. We are presenting a patient with atypical clinical and laboratorial presentation of multiple myeloma(MM): he was younger then expected for MM, without signs of infection and bleeding, with normal renal function, with hypercalcemia and not supressed level of PTH and elevated alkaline phosphatase. There was no radiographic signs of hyperparathyroidism. Biopsy of bone marrow demonstrated a infiltration with malignant myeloma-cells. A therapy with bisphosphonates was initiated.
